

EOCENE MAMMALS FROM IBERIAN PENINSULA

Miguel Telles ANTUNES¹, Maria Lourdes CASANOVAS², Miguel Angel CUESTA³,
Lluis CHECA², Josep Vicente SANTAFÉ² & Jorge AGUSTI²

ABSTRACT

A synthesis on the Iberian Peninsula Eocene mammalian record is presented here. Localities range in age from the Lowermost Eocene, MP 7 unit (Dormaal) until the Uppermost Eocene, MP 20 (Saint-Capraise). At present, 73 fossil sites in 12 basins are known. Faunal lists are given for each site.

Key-Words: Mammals, Eocene, Iberian Peninsula

RÉSUMÉ

MAMMIFÈRES DE L'ÉOCÈNE DE LA PÉNINSULE IBÉRIQUE

On présente une synthèse concernant les gisements à mammifères éocènes de la Péninsule Ibérique. Les gisements en question se rangent depuis l'Eocène basal, unité MP 7 (Dormaal) jusqu'à l'Eocène terminal, MP 20 (Saint-Capraise). Jusqu'à présent on connaît 73 sites, correspondant à 12 bassins. Pour chaque localité on présente la correspondante liste faunique actualisée.

Mots-clés: Mammifères, Eocene, Péninsule ibérique

INTRODUCTION

Mammals are one of the key groups in Paleontology. Their importance is critical for continental Stratigraphy and Paleogeography.

This is especially true for Eocene times and for the Iberian Peninsula. What is now the Iberian Peninsula (well before the accretion that resulted from the Betic collision in the Lower Miocene) was progressively being abandoned by the sea. This regressive process took place by Late Cretaceous and later, in the frame of a generalized post-Cenomanian tendency.

Meanwhile there was the uplift of the Pyrenees and other mountain ranges as the Central Iberian Chain. Increased erosion and transport during and after the Pyrenean paroxysmal phase in the lower part of the Upper Eocene resulted in the infilling of adjoining basins. Hence the importance of the Eocene formations, mainly in the Pyrenean region, elsewhere in Catalonia, in the Duero basin and its more or less related depressions in Portugal-North of the great fractures that limit the Central Chain.

The evolution of the geologic knowledge proceeded in Spain and Portugal. Sometimes there has been good cooperation, but research was often carried on with rather poor reciprocal knowledge. We therefore think a synthesis on the Eocene Iberian mammals is useful.

Pioneer work had been done in Spain, including that by F. Roman, and later by M. Crusafont and J. de Villalba. One of us (M.T.A.) is glad to acknowledge his interest on this field and on eventual developments in Portugal aroused from the *IV Cursillo Internacional de Paleontología* he attended at Sabadell in 1958.

Iberian faunal peculiarities may be ascribed to different environments and maybe to paleogeography.

Comparative studies on similar faunas from France and from elsewhere (as North Africa) will be even much more needed. Migrations and Paleogeography should be better known.

HISTORY OF THE KNOWLEDGE ABOUT IBERIAN EOCENE MAMMALS

The knowledge on Iberian Eocene mammals progressed a lot in the last decades. However some discoveries have been made in the 19th century.

SPAIN

- DUERO basin (concerned Portuguese basins being related to this large one)

The first reference to Spanish Paleogene vertebrates has been made by Gervais (1859). However the first sure account about vertebrates in the Duero basin (near Sanzoles) pointing out to a paleogene age, is that by Vilanova (1873).

Gil y Maestre (1880) and Puig y Larraz (1883) dealt with the geology of the Tertiary in the Salamanca and Zamora regions. Mammalian bones from Villamayor were reported by Calderon (1902). Sometime later, Miquel (1906) reported on remnants collected at San Morales that A. Gaudry ascribed to *Palaeotherium minus* and *Xiphodon gracile*, among other forms. This confirmed the presence of Paleogene. New fossils were collected at Corrales del Vino (Zamora), summarily referred

to by Hernandez-Pacheco (1915) and described by Roman & Royo y Gomez (1922), the Corrales site being regarded as Lutetian, Middle Eocene in age.

Taking into account previous work, Hernandez-Pacheco (1943) distinguishes Lutetian deposits at Corrales and Ludian ones near Salamanca. In the same region at Cabrerizos, Aldealengua and Aldearrubia, palaeotherids and an hypothetical creodont indicated a Ludian age; the presence of a Palaeotherid at Sanzoles is referred (Crusafont & Truyols 1957).

Still later, there has been an increase of papers on Stratigraphy, Sedimentology and Paleontology, more or less quoting earlier contributions. New discoveries were made. At Babilafuente near Salamanca, two rodents suggest an age close by that of the Robiac site in France (Lopez 1982).

Since 1988, M.A. Cuesta undertook the study of the Eocene mammals from the Duero basin near Salamanca, Zamora and Soria. The Mazaterón site was reported for the first time (Cuesta 1991, 1993). Data on new paleogene mammalian taxa from the Duero basin were presented (Jiménez *et al.* 1989; Pelaez-Campomanes *et al.* 1989).

There are further contributions concerning Paleogene sites by Cuesta (1991, 1993, 1994a, 1994b, 1994c, 1996) and by Cuesta *et al.* (1993, 1994); a new locality at Fuentesaúco (Zamora) close by the Middle-Upper Eocene limit in age was found.

- OVIEDO basin

The Oviedo basin's continental, Tertiary infillings were recognized by Barrois (1878) on the basis of a freshwater mollusk faunula ascribed to the Upper Eocene. Nevertheless, Mallada (1904) still reported these sediments to the Cretaceous, as it was done in all geologic maps of Spain until that of Asturias by Cueto in 1926 (Truyols & García-Ramos 1991).

The only vertebrate site, Llamaquique, discovered in 1926, clearly demonstrated a Tertiary age (González & Gómez de Llarena 1926). Some remnants were ascribed to *Palaeotherium magnum* by Royo y Gómez (1927), who reported on other Llamaquique fossils (Royo y Gómez 1928).

No further work on mammals was done until 1987; only a chelonian had been described (Bergouinioux 1957; Jiménez 1977). Then the study on the Eocene mammals from Llamaquique proceeded again (Casanovas & Santafé 1987, 1989, 1992; Moya-Sola 1992).

- CALATAYUD-TERUEL basin

Sierra Palomera's Paleogene continental formations and their biostratigraphic status within the frame of the eastern parts of the Iberian Cordillera were dealt with by Adrover *et al.* (1983), and Peláez-Campomanes (unpubl. thesis 1993), who studied late Upper Eocene rodents from Sierra Palomera and Villarrosano 1 and 12.

- UPPER TAJO basin

A breccia with bones was discovered in the Huérmece area, Guadalajara (communication to the Sociedad Española de Historia Natural presented May 6th, 1931 by Bargalló). After a visit to the site, Royo y Gómez reported it to the Upper Eocene.

The same site was rediscovered in 1957. Its age was then believed to be Upper Tertiary/ "Pontian" (Riba 1957, V INQUA Congress Field Guide).

Vertebrates were collected at Huérmece del Cerro, including *Palaeotherium crassum* and

Palaeotherium magnum; an upper Ludian age was accepted as possible (Crusafont, Meléndez & Truyols 1960). The same locality was referred again by Antunes (1964); Franzen (1968); Casanovas & Santafé (1987).

- SOUTH-PYRENEAN depression

Western, Central and Eastern basins may be recognized in this depression, the Central or Tremp, Jaca and Pamplona basin being the better known. It may subdivided into the Ager, Tremp-Graus, Isàbena and Pobla de Segur sub-basins.

Mammals and other vertebrates were reported in 1956 (*Boletín A.E.P.V.*, nº 4-5, Sabadell) after specimens from several sites (Crusafont & Rosell 1965). Age was not known. Later on, M. Crusafont and collaborators found other sites. Even if the material was rather poor, it was ascribed to the Upper Cuisian and the Lower Lutetian (Crusafont *et al.* 1968).

The same beds have been referred by several authors, and lately by Checa (1994) after new exploitation and collecting.

The Tremp-Graus sub-basin comprises the Montllobar and Pont de Montanyana areas (Checa 1994). The presence of continental beds was suspected since 1934 (Golpe 1971). A mammal was described (Crusafont & Villalta 1954). Since then, continental Eocene was found at several points at the Sierra de Montllobar. The lower beds yielded a mammal at Barranc de Forals (Crusafont 1956). (For more details see Crusafont, Villalta & Truyols 1956). Collecting was resumed in 1990, and up-to-date faunal lists concerning this Area and other Pre-Pyrenean sub-basins were given (Checa 1994).

Continental Eocene from Pont de Montanyana was exploited following geologic mapping by Malec (from Mainz), in which the so-far known sites are shown (Crusafont 1958; Golpe 1971; Crusafont & Casanovas 1973; Crusafont & Golpe 1973, 1974). Field work continued in 1990.

Collecting in the Isàbena sub-basin was carried on the Capella lignite mines (Golpe 1971). A Lophiodontid mandibular fragment was reported (Crusafont 1958). This and another fossil sent Crusafont by Meléndez induced the beginning of the study of the Capella mine. Further sites were found in the same sub-basin and reported since 1959 (Checa 1994).

The earliest site discovered in the La Pobla de Segur sub-basin (Collegats Formation) is Sossís. This and Roc de Santa are the richest continental

Eocene localities in the Pre-Pyrenean depression in Catalonia. Following a visit to the mine, the Sossís site was referred to (Bataller 1942). Sossís lignite was once regarded as Cretaceous, and later as Oligocene. The fossils obtained by Bataller suggested him an Upper Eocene age, although this has only been corroborated through the identification (Villalta & Crusafont 1944) of *Palaeotherium magnum*.

From the sixties on, research was extended to marls intercalated with lignite beds. Marls yielded mammal remnants (Checa & Casanovas 1989-90).

Washing and sieving techniques were introduced in Spain by L. Thaler and J.-L. Hartenberger (Montpellier). A large number of micromammals (rodents, insectivores, primates, etc.) was collected. Small mammals contributed to ascribe the Sossís lignites to the lower Ludian, Fons 4 zone. Sossís fossils were described in some doctoral theses, mostly by french authors. Mammalian remnants have been revised by Casanovas, Checa & Santafé (paper on Perissodactyla in press). Other articles on rodents, insectivores, primates, etc. are also in press.

Another site in the same area in the La Pobla de Segur sub-basin is Roc de Santa, discovered (1970) by staff of the Instituto de Paleontología de Sabadell and excavated until 1974. Age is the same as for Sossís. Dental material was studied by Casanovas-Cladellas (Barcelona Univ. thesis 1975); post-cranial bones were dealt with by the same author in collaboration with Santafé & Checa (several papers). Still later, washing and sieving allowed the recovery of large numbers of micromammal remnants.

Eocene mammals have been found in the Eastern basin by Busquets *et al.* (1992). Busquets has shown the sites to the staff of the Instituto de Paleontología de Sabadell; large amounts of specimens were collected. Checa-Soler (Barcelona Univ. thesis 1994) dealt with the Perissodactyla. Additional material is under study.

- EBRO basin

The Eastern or Catalánides sector was prospected by F. Colombo. The collected material is under study by researchers of the Instituto de Paleontología M. Crusafont (several papers; Checa, Thesis 1994).

- CENTRAL CATALONIAN basin

Generally poor Eocene sites with mammalian

remnants are known since long ago. The site at Sant Cugat de Gavadons, Moyà sub-basin, was exploited by the Instituto de Paleontología M. Crusafont staff during the sixties and seventies; it yielded an interesting assemblage of Upper Eocene macro- and micromammals.

PORTUGAL

- MONDEGO basin
- LOUSÃ basin
- LESSER DEPRESSIONS IN THE BEIRA ALTA PENEPLAIN

The first studies where Paleogene units are referred were focused on the Lower Tagus basin, where no vertebrate fossils are known; the earliest seems to be a memoir by Baron Wilhelm-Ludwig von Eschwege (Eschwege 1831), where he refers the "Conglomerados, que se achão no *Valle de Benfica e Porcalhota*" (p. 262 and geologic section; this corresponds to the unit subsequently named *Complexo de Benfica*). Near Lisbon, the *Complexo de Benfica* is comprised between the underlying *Complexo vulcânico de Lisboa-Mafra* and the marine, Lowermost Miocene.

Under the influence of Paul Choffat (Choffat posthumous paper 1950; and earlier contributions), the post-Cenomanian *Complexo vulcânico*, and the *Complexo de Benfica* were regarded respectively as Eocene and Oligocene in age. This largely conjectural opinion was generally accepted, and an Oligocene age was assigned to other continental units elsewhere in Portugal supposedly correlative to the *Complexo de Benfica*.

Meanwhile, Rb-Sr dating demonstrated a Late Cretaceous age for the *Complexo vulcânico*, while stratigraphic correlation (mainly based on feldspar-rich sands that probably have been distally deposited after the paroxysmal Pyrenean event) suggested instead an Eocene age for the lower subunits of the *Complexo de Benfica* (Antunes 1979).

Actual data on Eocene vertebrates concern sites North of the great fractures (i.e. the Nazaré accident) that limit the Central Chain, where several Eocene units and sites are known (Ginsburg & Zbyszewski 1965; Antunes 1975, 1979). No Oligocene ones were recognized.

The first fossil mammals were collected at Côja. However their true nature and age were not recognized until later, when the presence of an Upper

Eocene paleotherid was shown for the first time in Portugal (Antunes 1964). Other papers followed (Antunes 1967, 1986b, 1992; Antunes & De Broin 1977).

Later Middle and early Upper Eocene discoveries were made at the coast North of Nazaré at Vale Furado and Feligueira Grande (Antunes 1986a, 1995). A major discovery of an earliest Eocene (or

late Paleocene?) vertebrate fauna at Silveirinha, Baixo Mondego area, fully justified the launching (by M.T. Antunes) of a Research Program which is still in progress (Antunes 1981; Antunes & Russell 1981; Antunes, Estravís & Russell 1987; Estravís 1990, 1992, 1994; Estravís & Russell 1989, 1992a, 1992b).

BASINS, SITES AND FAUNAL LISTS

In our present state of knowledge, the Iberian basins and sites that yielded Eocene mammals are as follows, from West to East (Fig. 1).

[REMARKS: Lists are presented as given by authors, no revision or discussion was attempted; CAPITAL, countries, basins and subbasins; sites are in bold; approximate age is given, as well as MP, Paleogene Mammal-units.]

Overall similarities seem stronger than differences. More detailed comparative studies involving Spanish collections will be most useful. One will then be in a better position to ascertain how real are some of the Iberian faunal peculiarities. After all, the Pyrenees may not have been effective enough as a barrier as far as mammal migrations are concerned.

PORUGAL

As for portuguese material, comparisons have most often been made with French collections.

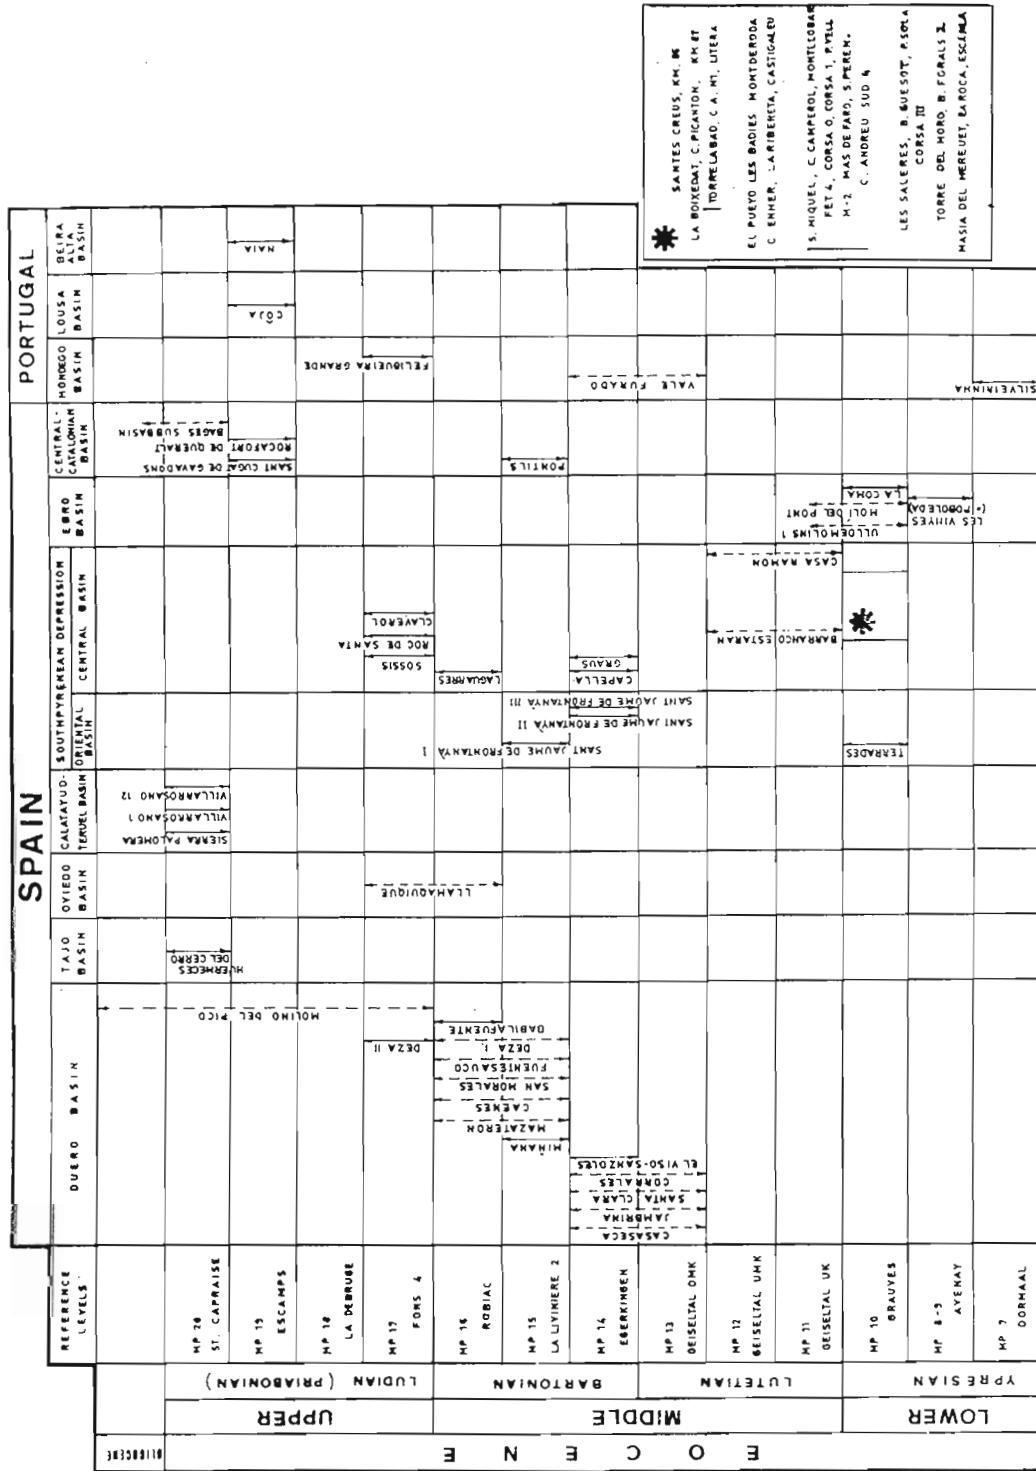

Figure 2.—Iberian Eocene mammal sites and chronology (Mammal-units from MP 7 / Dormaal until MP 20 / Saint-Capraise).

CONCLUSIONS

1. In our present state of knowledge, Iberian Eocene mammals range from Lowermost, MP 7 Dormaal mammal unit, until the Upper Eocene, MP 20 Saint-Capraise mammal-unit (Fig. 2).
2. The earlier fauna, only known from Silveirinha, is close to the Paleocene-Eocene limit; it cannot be excluded that it could be Late Paleocene in age.
3. There are several Lower Eocene sites in Spain, mainly in the Central basin of the South-Pyrenean Depression; reported to the MP 10 (Grauves) unit (34 sites).
4. The Middle Eocene faunas are represented in the Duero basin, with 12 localities ranging from MP 13 (Geiseltal Obere Mittelkohle) to MP 16 (Robiac); in Portugal, in the Mondego basin at Vale Furado the Middle Eocene levels may be ascribed to ca.. MP 13 or MP 14 (Egerkingen α+β); 5 localities, MP 14 to MP 15 (La Livinière) are known in the Eastern and Central basins of the South Pyrenean Depression.
5. The lower Upper Eocene yielded good material in the Duero basin at Deza, in Oviedo basin at Llamaquique, and in the Central South Pyrenean basin at Sossís, Roc de Santa and Claverol, MP 17 (Fons 4) unit; in the Mondego basin, a few fossils from Felgueira Grande may be reported to the same unit.
6. Still in Upper Eocene but after the paroxysmal Pyrenean event, there are some data from Côja, Lousã basin, and Naia, Beira Alta, in Portugal-MP 19 (Escamps); the same unit is represented at Sant Cugat de Gavadons and Rocafort de Queralt in the Central Catalonian basin.
7. The latest Eocene MP 20 (Saint-Capraise) unit faunas are represented in the Calatayud-Teruel basin at Sierra Palomera and Villarrosano; and probably in the Upper Tagus basin at Huérmeches del Cerro, and in the Bages sub-basin (Central Catalonian basin).
8. More data and accurate comparisons with more or less the same age faunas from France (and elsewhere in Europe) and North Africa are needed for interpretation of migration pathways, regional faunal differentiation, and ecology.

ACKNOWLEDGEMENTS

Acknowledgements are due to Colleagues who provided data that allowed us to update some of the faunal lists in this paper: Gloria Cuenca (Zaragoza University), Nievez Lopez and Pablo Pelaez Campomanes (Madrid University), Pere Busquets and Salvador Reguant (Barcelona University). We also acknowledge Mr. Angel Cuesta for the figures.
