THE EFFECT OF R&D INTENSITY ON CORPORATE SOCIAL RESPONSIBILITY

Robert Carlton Padgett Cooper

José Ignacio Galán Zazo

Abstract

This study examines the impact that Research and Development (R&D) intensity has on Corporate Social Responsibility (CSR). We base our research on the Resource Based View (RBV) theory, which contributes to our analysis of R&D intensity and CSR because this perspective explicitly recognizes the importance of intangible resources. Both R&D and CSR activities can create assets that provide firms with competitive advantage. Furthermore, the employment of such activities can improve the welfare of the community and satisfy stakeholder expectations, which might vary according to their prevailing environment. As expressions of CSR and R&D vary throughout industries, we extend our research by analysing the impact that R&D intensity has on CSR across both manufacturing and non-manufacturing industries. Our results show that R&D intensity positively affects CSR and that this relationship is significant in manufacturing industries, while a non-significant result was obtained in non-manufacturing industries.

Keywords:
Competitive Advantage, Corporate Social Responsibility, Industry, Resource Based View Theory, Research and Development.
1. INTRODUCTION

The importance of corporate social responsibility in managerial practice worldwide has encouraged academics to study its effects and how firms can or cannot obtain benefits from CSR practices. There has been a growing number of publications that study CSR, with mixed results and no clear understanding due to the vagueness and intangibility of the term (Frankental, 2001). Moreover, there are numerous definitions of CSR and often no clear definition is given in the studies, making theoretical development and measurement difficult (McWilliams, Siegel and Wright, 2006).

Another reason for the difficulty in measuring CSR is that the behaviours involved occur across a wide range of industries with significantly different characteristics, backgrounds, and performances in the different CSR domains (Graves and Waddock, 1994; Waddock and Graves; 1997). Thus, the difficulty of conducting research in the field of CSR is compounded and heightened by both its complexity and the fact that compared to other business functions its appearance as a legitimate area of enquiry in management literature is very recent (Harrison and Freeman, 1999).

This research builds on recent and very important studies that have investigated the relationship between CSR and the financial performance of firms. One of the most important findings helping researchers to measure this relationship accurately was reported by McWilliams and Siegel (2000), who proved that CSR is positively correlated with R&D intensity. Other research that corroborates this finding is the study conducted by Hull and Rothenberg (2008). We aim to study the impact of R&D on CSR closely to determine and explain the behaviour of this effect in order to provide insight for those who want to continue studying the relationship between CSR and financial performance, including R&D as a necessary variable in their models.
Previous studies, such as those by Berrone, Surroca and Tribo (2007), Bouquet and Deutsch (2008), Hull and Rothenberg (2008), McWilliams and Siegel (2000, 2001), and Prior, Surroca and Tribo (2008), have discovered that these variables are correlated when studying the impact of CSR and another variable. However, none of these researches have studied the direct impact of R&D on CSR, so we considered it necessary to study this effect in order to fill this gap in the literature.

The fundamental framework we have used as the basis for our study is the Resource Based View (RBV) theory, which can contribute to our analysis of R&D intensity and CSR because this perspective explicitly recognizes the importance of intangible resources, such as know-how, corporate culture and reputation (Russo and Fouts, 1997). Furthermore, other researchers agree with the use of RBV for studying these variables by stating that the usefulness of RBV in the study of CSR is due to the emphasis it places on the importance of specific intangible resources, as they are very difficult to imitate and substitute (Branco and Rodrigues, 2006).

Our research adopted a panel data methodology. This technique allows us to control the risk of unobserved heterogeneity on the manager’s conceptions of social responsibility and company strategy (Bouquet and Deutsch, 2008). Our main hypothesis states that R&D intensity positively affects CSR. We take a step forward in our second hypothesis by examining this effect between firms in manufacturing and non-manufacturing industries. We expect this effect to be stronger in firms in manufacturing industries, as previous studies such as the ones by Hadlock, Hecker and Gannon, (1991), positing that manufacturing industries have high R&D concentration, and by Hull and Rothenberg, (2008); McWilliams and Siegel, (2000); Rothenberg and Zyglidopolous, (2007), have stated that R&D intensive firms are likely to have high CSR.
This article contributes to the literature in several different ways: firstly, we are studying an effect between two variables that until now has not been studied in this way; secondly, we are studying the impact of one variable on the other between manufacturing and non-manufacturing industries; finally, we are using a panel data methodology that gives robustness to our research.

The remainder of the paper is organized as follows: the second section reviews the Resource Based View theory and the empirical evidence, and the hypotheses are presented; the third section describes the data and estimation method used in our analysis; the results are discussed in our fourth section and, finally, the fifth and last section presents our conclusions to this research.

2. THEORY AND HYPOTHESES

2.1. The Resource Based View and Competitive Advantage

The Resource Based View (RBV) was developed from the idea of the industrial organization (IO) view of the firm (Bain, 1959; Porter, 1980, Russo and Fouts, 1997), which stated that a firm’s success was wholly determined by external factors. Early resource-based researchers found this unrealistically limited and turned to Penrose (1959) for motivation in developing theories for the RBV of the firm (Russo and Fouts, 1997). To argue against the IO view of the firm, several theorists such as Dierickx and Cool (1989), Prahalad and Hamel (1990) and Wernerfelt (1984) constructed the resource-based theory stating that a firm’s success was not wholly determined by external factors but also by its internal characteristics.

According to the RBV, firms with assets that are valuable and rare possess a competitive advantage and may expect to earn superior returns, and those firms whose assets are also difficult to replicate may record a sustained superior financial performance (Barney, 1991; Grant, 1991; Roberts and Dowling, 2002).
Yet the RBV is not only about internal competencies and how they can generate competitive advantages; the firm is also affected by external factors. “Resources cannot be evaluated in isolation. A resource that is valuable in a particular industry or at a particular time might fail to have the same value in a different industry or chronological context” (Collis and Montgomery, 1995:120)

According to Grant (1991), resources are classified as tangible, intangible, and personnel-based. Tangible resources include physical resources such as infrastructure, equipment, raw materials, and financial reserves. Intangible resources include reputation and technology. Personnel-based resources involve such concepts as culture, training, commitment, loyalty and knowledge. None of these resources is productive on its own, but a combination of these is what will make the firm productive. (Russo and Fouts, 1997)

The RBV can contribute to our analysis of R&D intensity and CSR because this perspective explicitly recognizes the importance of intangible resources such as know-how, corporate culture and reputation (Russo and Fouts, 1997). Moreover, other researchers agree with the use of the RBV to research these variables by stating that the usefulness of the RBV in the study of CSR is explained by the emphasis it places on the importance of specific intangible resources, as they are very difficult to imitate and substitute (Branco and Rodrigues, 2006).

**Importance of CSR and R&D for Firms to Obtain Competitive Advantages**

We will begin by giving the definition of CSR used by McWilliams and Siegel (2001), whereby CSR involves those situations in which the firm takes part in “actions that appear to further some social good, beyond the interests of the firm and that which is required by law” (117:2001). It has been proven that a high level of CSR is a strategy that firms can use to differentiate themselves (Hull and Rothenberg, 2008; Mackey, et. al., 2007; Siegel and Vitaliano,
2007) in order to obtain certain competitive advantage. Moore (2001) and Harrison and Freeman (1999) make an important point when they state that social performance and economic performance should not be separated, since in order to determine whether a firm is “good”, it has to perform well on both counts. Research and development (R&D) is another way a firm can obtain competitive advantage (Hull and Rothenberg, 2008), with the long-standing theoretical literature linking investment in R&D with improvements of the firm in the long run (McWilliams and Siegel, 2000; Griliches, 1979).

CSR can be viewed as a type of investment used as a mechanism for product differentiation, where CSR can be positioned in the context of ‘resources’, in which CSR policies would help to improve processes for developing products and services, and of ‘outputs’, where CSR policies and attributes would have a direct impact on a firm’s product. For example, firms can maintain a level of CSR by having products with “CSR attributes (such as pesticide-free fruit) or by using CSR-related resources in their production processes (such as naturally occurring insect inhibitors and organic fertilizers)” (McWilliams and Siegel, 2001). It has been found that the introduction of new and improved processes and products is positively related with R&D intensity (Hitt, Hoskisson, Johnson, and Moesel, 1996). Innovative strategies employed by firms have a substantial impact on processes; in order to create new products and services that have a competitive advantage, they must meet the four criteria described by the RBV theory, namely, they should be valuable, rare, inimitable, and the organization must be organized to deploy these resources effectively (Barney, 1991). Using these criteria, resources that may lead to a competitive advantage include socially complex resources such as reputation, corporate culture, long-term relationships with suppliers and customers, and knowledge of assets (Barney, 1986; Hillman and Keim, 2001; Leonard, 1995; Teece, 1998)
At the same time, researchers contend that it is important for businesses to look beyond their narrow focus of social responsibility and take social concern into consideration in strategic management decisions, as this will ensure business interests in the long term by creating a close bond with their community (Carlson, Grove and Kangun, 1993; Quazi and O’Brien, 2000). Further research shows that consumers prefer products and invest in firms that care for the environment and maintain good citizenship behaviour (Zaman, Yamin and Wong, 1996; Gildia, 1995; Quazi and O’Brien, 2000), which helps the firm to build a good reputation and image as valuable resources that can create a competitive advantage for it.

Schnietz and Epstein (2005) agree with McWilliams and Siegel (2001) and Lantos (2001) in that CSR creates a reputation that a firm is honest and reliable, giving financial value to the firm. In response to this reputation, consumers will typically assume that the products of these types of firms are of good quality, and they become difficult for other firms to imitate. In addition, firms in industries with skilled labour shortages have used CSR as a means to recruit and retain workers. Brammer and Pavelin (2006) state that depending on a firm’s industry and environment, social responsibility actions must vary in order to fulfil general stakeholder expectations and build a good reputation.

At the same time, firms can profit through the use of R&D, since R&D intensive industries usually have ‘entry barriers’ where companies can achieve effects such as economies of scale and product differentiation (Porter, 1979). These effects help firms to obtain a competitive advantage over other firms. How R&D investment affects firm productivity is a question that is of considerable interest to several researchers. There is the seminal work by Griliches (1981) and his hedonic model based on US firm-level data, which used market value as an indicator of the firm’s productivity from investments in R&D. Several other researchers have used this same model to
prove that there is a positive relationship between R&D investments and the market value of the firm (Cockburn and Griliches, 1988; Hall, 1993; Hirschey, 1982; Jaffe, 1986).

R&D is considered to be a form of investment in ‘technical’ capital that results in knowledge enhancement, which leads to product and process innovation. This innovative activity allows firms to enhance their productivity (McWilliams and Siegel, 2000). Studies such as those by Ben-Zion (1984), Clark and Griliches (1984), Griliches (1998), Guerard, Bean and Andrews (1987), Hall (1999) and Lichtenberg and Siegel (1991) report similar results that confirm a positive correlation between R&D investment and firm growth. Investment in R&D involving innovation related with CSR processes and products is attractive to some consumers, such as recycled products or organic pest control. McWilliams and Siegel (2001) stated that using a differentiating strategy in order to obtain a competitive advantage through the use of CSR resources may also include investment in research and development (R&D).

McWilliams and Siegel (2000) proved that CSR is positively correlated with R&D intensity “because both are associated with product and process innovation” (2000:607). If CSR and R&D are highly correlated, an equation that includes CSR and does not include R&D intensity as determinant of a firm’s performance will turn out to be upwardly biased. Other researchers have also suggested that R&D should be included as a moderator in theoretical models that have received mixed or ambiguous empirical support (Han, et. al., 1998; Hull and Rothenberg, 2008).

Therefore, a longitudinal study of the interactions between R&D intensity and CSR variables is called for (Hull and Rothenberg, 2008), as one that will provide insight and facilitate an understanding of the interaction that exists between these two variables.

Based on the above arguments, we therefore suggest the following hypothesis:
**H1: R&D intensity positively affects CSR.**

Earlier research (Graves and Waddock, 1994) has shown that there are clear differences between different industries in levels of investment in R&D (Waddock and Graves, 1997). Furthermore, the characteristics of a firm’s industry have been hypothesized to be a key influence on its social performance (McWilliams and Siegel, 2000), since industries differ according to the stage of the product lifecycle they are in. The use of CSR as a differentiation strategy will be present depending on the industry’s lifecycle, since little product differentiation is expected in the embryonic and growth stages because firms are focused on perfecting processes and satisfying growing demands (McWilliams and Siegel, 2001). Some industries will be young and companies active in them will have a range of alternative investment projects, whereas mature industries offer fewer alternative investment opportunities to their companies. (Brammer and Millington, 2008) In addition, depending on the industry, companies may have a different view of CSR actions and the way they are implemented in their R&D processes. Quazi and O’Brien (35:2000) state that “the broader dimension of social responsibility, therefore, calls for innovation in production and marketing to reap the benefits of proactive social action”. The authors give the example of pollution control and how some companies consider it to be an unnecessary expense, thereby perceiving it negatively in financial terms. Meanwhile, other firms may argue that pollution is a sign of inefficiency and flawed technology that also costs the firm money and affects the community. This second perspective is supported by Ahmed, Montagno and Flenze (1998), who have found that environmentally friendly companies have better productivity and profitability than non-environmental firms.

R&D intensity varies according to the industry, and is usually more intense in manufacturing industries than in non-manufacturing ones. For example, the automotive industry has initiated
intensive R&D programmes in order to develop a new kind of technology-based competition in response to current environmental changes, long-term increases in petrol prices and regulatory efforts to curb the threat of global climate change (Khaledabadi and Magnusson, 2008).

These types of changes and increasing stakeholder pressure on firms to tackle social issues are driving more and more companies to engage in CSR activities (Quazi, 2003). Moreover, R&D intensive industries such as pharmaceuticals may face particular incentives to engage in CSR activities that boost the long-term supply of highly skilled labour. (Brammer and Millington, 2008) Another reason that manufacturing industries might increase their CSR activities is that, according to Nicolleti and Scarpetta (2003), there are more industry-specific regulations are in manufacturing industries than in non-manufacturing ones.

Williamson, Lynch-Wood and Ramsay (2006) state that manufacturing processes have significant economic and environmental impacts, which have led firms to develop CSR practices that favour our environment. Many firms are adopting voluntary environmental management systems, signing international agreements such as the UN Global Compact, or have joined local projects to minimise waste. “These trends have largely been driven by an increasing demand for “transparency” from stakeholders, and perceived consumer demand for environmental quality” (Chapple, Paul and Harris 348:2004). These national and industry forces create environments in which stakeholders and local competitors have different expectations of what the appropriate levels and types of corporate citizenship should be (Gardberg and Fombrun, 2006), with more pressure being placed on manufacturing industries because they are believed to use up more resources, create more waste and have a higher intensity of R&D activities than their non-manufacturing counterparts simply because of the nature of their processes.

Consequently, we decided to look for differences in the intensity of the impact of R&D on CSR activities between manufacturing industries, which are those that are acknowledged to have
a high intensity of R&D, and non-manufacturing ones. To do so we developed the following hypothesis:

\[
H2: \text{R&D intensity positively affects CSR with a higher intensity in manufacturing industries than in non-manufacturing industries.}
\]

3. METHODS

3.1. Data and Sample

In order to associate R&D intensity with CSR we needed data to create a single database on how firms interact with their stakeholders and society along with corporate financial data. The corporate financial data are taken from Thomson’s Datastream and the CSR data are from KLD Research and Analytics, Inc.

Over 40 peer-reviewed articles, representing a variety of academic fields (including finance, economics, management and sociology) have used KLD data to research companies’ social, environmental and governance performance (KLD, 2008). Some of these articles are: Cuesta-González, et al., 2006; Hull and Rothenberg, 2008; Márquez and Fombrun, 2005; McWilliams and Siegel, 2000; Schnietz and Epstein, 2005; Waddock and Graves, 1997.

KLD uses screens to monitor corporate social performance (see Sharfman, 1996, for an assessment of data validity). These screens are divided into positive and negative ones, with positive ones signifying company strengths and negative ones signifying company weaknesses. The screens are divided into groups that reflect the firm’s general corporate social performance.

The period researched has a span of 16 years, from 1991 to 2007. We excluded companies with missing data, and in order to perform our analysis we divided our sample into three groups. The first model comprised 5,799 observations and 1,217 companies, which is used to explain
Hypothesis 1; the second and third models were developed to explain Hypothesis 2, where the second model contained only manufacturing companies and comprised 2,724 observations and 575 companies, and finally, the third model contained non-manufacturing companies and comprised 3,075 observations and 642 companies.

### 3.2 Measures and Estimation Method

KLD data are designed as a binary system. For each strength or concern in each variable, rating 1 indicates the presence of a strength or concern, while 0 indicates its absence. For the first hypothesis, CSR is our dependent variable, where we used KLD data to develop the same scale used by Hillman and Keim (2001), which is also used by many other authors (Cuesta-González et al, 2006; Hull and Rothenberg, 2008). The CSR rating is scored using a scale ranging from -2 (major concerns), -1 (concern), 0 (neutral), +1 (strength), to +2 (major strength). To check the robustness of our models, we replaced the CSR scale that ranges from -2 to 2 with an alternative specification of the dependent variable, as used in industrial organization and strategy research (Kortum and Lerner, 2000), which is equal to the logarithm of the sum of strengths plus 1 (Kacperczyk, 2008). We obtained a significant result with both measures. We refer to this variable as CSR+ in our results tables.

*R&D intensity* is our independent variable, where we use a proxy of R&D, calculated by dividing total expenditure on R&D by total sales, basing our study on measures used by McWilliams and Siegel, (2000), Bouquet and Deutsche (2008), and Prior, Surroca and Tribo (2008) which showed that R&D is positively correlated with CSR. Other research that has corroborated the correlation between these two variables includes the study by Hull and Rothenberg (2008), which measured R&D using a 3-year average of R&D expenditures, and yet
another study that has recorded the same finding as the studies mentioned above, Berrone et al. (2007), who measured R&D intensity as R&D expenditures to total assets on a log scale.

We include several control variables in our model. We used *company size* because previous articles have suggested that it is closely related to CSR (Johnson and Greening, 1999; Udayasankar, 2008; Waddock and Graves, 1997). To measure company size in our analysis we used net sales (Brammer and Millington, 2008; Kacperczyh 2008) and number of employees (Berman, et. al., 1999), both defined on a log scale.

We used *ROA* (return on assets) as a control variable as well, as it yields the most direct information about the results in the allocation of resources by a firm as it seeks competitive advantage (Hull and Rothenberg, 2008). *ROA* is calculated as *operating income over total assets*.

In addition, we included *Risk* as a control variable, since several studies have found that a firm with proactive CSR engages in managerial practices, such as stakeholder management (Wood, 1991), which tend to anticipate and reduce potential sources of business risk, such as potential governmental regulation, labour unrest, or environmental damage (for details see: Orlitzky and Benjamin, 2001). As a proxy for management risk tolerance, we use the level of debt held (*total debt to total assets ratio*) by the firm (Hull and Rothenberg, 2008).

For our second hypothesis we analyze the same effect as in our first hypothesis, but we divide our sample using SIC industry classification into manufacturing and non-manufacturing industries, to determine where this relationship is more intense.

We used the panel data methodology to estimate our models. Unlike cross-sectional analysis, panel data analysis allows us to control every firm and has its own specificity that gives rise to a particular behaviour closely linked to the company’s strategy. This choice was motivated by the importance of considering significant problems that arise when studying the influence that R&D intensity has on CSR.
Unobserved variables can be eliminated by specifying a fixed-effects or a random-effects model, as several sequential (yearly) observations of the same company are recorded. More specifically, given the longitudinal data on firm R&D intensity for firm $i$ at moment $t-1$ on CSR at moment $t$ can be modelled as follows:

$$
CSR_{it} = \alpha + \beta \cdot R&D_{it-1} + \beta \cdot ROAi_{t-1} + \beta \cdot salesi_{t-1} + \beta \cdot employeei_{t-1} + \beta \cdot riski_{t-1} + n_i + v_{it}
$$

Where $CSR_{it}$ is firm $i$’s CSR associated with the current year; $R&D_{it-1}$ is the R&D intensity of firm $i$ associated with the previous year; $ROAi_{t-1}$, $salesi_{t-1}$, $employeei_{t-1}$ are control variables for firm $i$ associated with the previous year; $n_i$ is a time invariant firm specific error that captures the effects of unobservable characteristics; $v_{it}$ is the error term. It is important to note that the models also incorporate a yearly trend variable to account for differences over time.

4. **RESULTS**

Table 1 provides the descriptive statistics (mean and standard deviation) of our three models with both measurements of CSR that we used in our research to make our analysis more robust. It shows the dependent variables CSR and CSR+ in year $t$ and all independent variables in $t-1$. One can also observe the sample size of all models and the number of firms, with a total of 5,798 observations and 1,217 firms in model 1. Our model 2, which considers firms in manufacturing industries, has a total of 2,724 observations and 575 firms and, finally, our model 3, which considers firms in non-manufacturing industries, has a total of 3,074 observations and 624 firms.

Sample Size: 5798, 2724, 3074
Number of Firms: 1217, 575, 624

CSR+ = \log(\sum \text{strengths} + 1); CSR = Scale ranging from -2 to +2; R&D = R&D to total sales; ROA = Return on Assets; Net Sales = Logarithm of net sales (proxy for size); Employees = Logarithm of employees (proxy for size); Risk = Total Debt to Total Assets Ratio
All independent variables are in t = -1

Table 2 shows the correlation matrix for the total sample. There is a negative significant correlation between the size control variables (net sales and employee) and ROA with both our measures of CSR. As can be seen, we were unable to find a significant correlation between R&D and any measure of CSR, although the impact of R&D on CSR in the panel data analysis is positive and significant in both model 1 and model 2.

*p<0.10; **p<0.05; ***p<0.01
Table 3 presents the results of the panel data analysis for our three models using CSR as our dependent variable and R&D as explanatory variable, controlling for size (net sales and employees), ROA and risk, using a 1-year lag between CSR and all independent variables. As can be observed in Model 1, R&D, Net Sales and employees are significant, whereas ROA and risk variables are not. The effect that R&D has on CSR is positive at a significance level of p<0.01, and model 1 has an R-squared within 0.0414. When we performed the Hausman Specification Test to determine whether or not to use a fixed-effects model or a random-effects model in our analysis, we obtained a negative result. In view of this negative result, we had to perform the Sargan-Hansen statistic, which resulted in 54.887, thus the model of choice for our analysis is a fixed-effects model.

Table 4 shows the results of the panel data analysis for our three models using CSR+ (our second measure of CSR) instead of CSR. Model 1 obtained similar results in Table 4 as it did in Table 3, where R&D also affects CSR+ in a positive way at a p<0.01 level. These results confirm our first hypothesis, where we state that R&D intensity affects CSR in a positive way.

Table 3 also shows the results of our panel data analysis for Model 2, where we include firms in manufacturing industries only, and the results for our Model 3 analysis, where we include firms in non-manufacturing firms only. Here we found that R&D intensity positively affects CSR at a p<0.01 in Model 2, while Model 3 displays no significance in the effect that R&D intensity has over CSR. After performing the Hausman Specification Test for Model 3, the result showed
no significant correlation between the unobserved person-specific random-effects and the regressors, so the random-effects model may be more powerful and parsimonious, thus being our model of choice for Model 3, while the results of this test determined that we should use a fixed-effects model for Model 2.

Table 4 shows similar results between this effect in Model 2 and Model 3 and our other measure of CSR+. However, with this measure of CSR+, the Hausman Specification Test indicated that we should use a fixed-effects model instead of a random-effects model for both Model 2 and 3. These results confirm our second hypothesis, which states that R&D intensity impacts CSR to a greater degree in manufacturing industries than in non-manufacturing industries.

5. DISCUSSION AND CONCLUSION

The RBV theory allows us to analyze the effect of R&D intensity on CSR because, as we stated before, this theory explicitly recognizes the importance of intangible resources, which are difficult to imitate and substitute. As discussed previously, both CSR and R&D possess characteristics that are consistent with the RBV theory, making them very important resources that will allow a firm to achieve a competitive advantage and at the same time benefit society. Given the importance of these resources in a firm’s performance, many studies have focused on understanding the relationship between CSR and financial performance or between R&D and financial performance. Recent studies have shown that in order to measure accurately how CSR affects a company’s financial performance, R&D must be included in the study so that the results do not give an upwardly biased estimate of the CSR variable (McWilliams and Siegel, 2000). Several previous studies have also found a significant correlation between these two resources, so it is important to understand the effect that one has over the other.
The results of this research provide support for our first hypothesis, which states that R&D intensity affects CSR in a positive way. R&D is considered to be a form of investment that results in knowledge enhancement, leading to product and process innovation. These product and process improvements can lead to CSR-related processes and products. For example, R&D activities might improve processes and make them more effective, which can also reduce the amount of energy the firm consumes, with the ensuing cost reductions and less pollution. Such activities should also be taken into account as CSR actions of the firm. Previous research has shown that these two variables depend on the industry they are in, so consistent with our reasoning that product and process innovation brings CSR activities to the firm, we decided to test this effect in both manufacturing and non-manufacturing industries. Our results show that the effect that R&D intensity has on CSR is positive and significant in manufacturing industries, while in non-manufacturing industries R&D intensity has no significant effect on CSR. This finding shows that firms in industries with a higher intensity of R&D also devote efforts to CSR activities. This result might be explained by the fact that manufacturing industries are under more pressures from stakeholders and government policies to carry out CSR activities. Even if this might be true, some firms always choose to exceed stakeholder expectations and policies by engaging CSR actions that minimise waste and reduce energy consumption, and by initiating progressive human resource management programmes (Chapple, Morrison and Harris, 2004).

The academic value of this research is that it has filled a gap in the literature, since to our knowledge there has been no other study that focuses on understanding the effect that R&D intensity has on CSR as we proposed, and our model was estimated using panel data techniques, which are better capable of controlling for inherent heterogeneity than a simple regression. The results of this study enforce previous research that states the importance of taking R&D intensity
into consideration when studying the relationship between CSR and a firm’s financial performance.

The managerial value of this study is that firms need to take their R&D activities into consideration when developing their CSR strategy, since process and product innovations may already be involved in CSR activities. Thus, innovative firms should focus their efforts on identifying opportunities in their R&D processes to initiate related CSR activities. This will allow the company to manage costs more effectively and determine whether other CSR activities might be necessary to meet stakeholder expectations. This is important for managers following differentiation strategies by investing in R&D and CSR, since they are related activities that provide a firm with a competitive advantage. In addition, firms should make an effort to ensure that they “are a part of a larger society with a wider responsibility reaching beyond the narrow perspective of profit” (Quazi and O’Brien, 33:2000), which is an opportunity for building a sustainable relationship with stakeholders (Polonsky et al., 1997; Quazi and O’Brien, 2000).

For further research it might be interesting to study the effect that R&D intensity has on the CSR of individual manufacturing industries, since this effect might be stronger or weaker depending on the characteristics of the industry. Furthermore, because of CSR’s complexity, a study of the effect that R&D intensity has on different CSR dimensions might provide broader insight and understanding of this effect.
