Abstract

In this paper we describe the moduli space of kinks in a class of systems of two coupled scalar fields in (1+1) Minkowski space-time. The main feature of the class is the spontaneous breaking of a discrete symmetry of (real) Ginzburg-Landau type that guarantees the existence of kink topological defects.

1 Introduction

Research into the mathematical properties and physical meaning of topological defects in relativistic field theory has increased sharply since the mid seventies of the twentieth century. There has also been a parallel development in (non-relativistic) condensed matter physics. Extended states and phase transitions - e.g. type II superconductivity - are related to the appearance of such exotic phenomena. Domain wall defects in the real world can be thought of as solitary waves propagating in a (1+1)-dimensional universe that self-replicate in the remaining two dimensions. Thus, investigations on kink nature and behaviour in $(1+1)_2$ or sine-Gordon models inform us about the properties of the simplest type of topological defect. Realistic theories, however, involve more than one scalar field and the study of $(1+1)$-dimensional $N$-scalar field models in this respect is not only worthwhile but also mandatory. Examples of theories with $N > 1$, where one might be interested in looking at topological defects, include the linear sigma model, the Ginzburg-Landau theory of phase transitions, the supersymmetric Wess-Zumino model, SUSY QCD, etcetera.

Kinks are time-independent nine-energy solutions of the field equations that have been thoroughly investigated in the $N = 1$ case, see e.g. [1]. Much less is known about the kink variety in systems with two or more scalar fields (the reason for this is also clearly explained in [1]). To the best of our knowledge, however, there are exceptions:

A deformation of the linear $O(2)$-sigma model, christened in the literature as the M STB model, exhibits a rich variety of kinks. The characteristics of any of these kink defects as well as the structure of the variety as a whole have been elucidated in a long series of papers, see References [2-12]. The moduli space of kinks in an analogous deformation of the linear $O(3)$-sigma model has also been fully described in [13].
The search for kinks is tantamount to the solving of a mechanical problem, which is seldom solvable if $N = 2$. In [14] we described the kinks of two $N = 2$ eld-theoretical models associated with completely integrable mechanical systems; i.e., the same idea that works in the M STB model and its $N = 3$ generalization.

In [15], the kinks of the Wess-Zumino model are shown to be given by certain real-algebraic curves in the complex plane.

Another favorable situation occurs when the eld-theoretical model is the bosonic sector of a supersymmetric system. This is the case of the Wess-Zumino system and also happens in a $N = 2$ model proposed in [21], which has been discussed and applied to describe several interesting physical contexts in the series of papers [16-25]. Throughout their work, Bazelia et al. identify only two kinds of kinks: a topological one, with only the rst component non-null, usually termed as the TK1 kink, and a second topological kink that has both components non-null and is called the TK2 kink. In contrast with the M STB model, where the TK1 kinks are unstable, [14]-[15], and decay to the TK2 kinks, [14], in the system of Bazelia et al. there is an interesting phenomenon of kink degeneracy: the TK1 and TK2 kinks have the same classical energy.

The main result to be shown in this paper is that the kink degeneracy is a continuous one rather than the discrete degeneracy implicit in [16-25]. We shall nd a continuous family of kink solutions to the classical eld equations, all of them degenerated in energy with the TK1 and TK2 kinks. The existence of this variety of kinks is possible because of the spontaneous breaking of a discrete internal symmetry group. The quotient of the kink variety by the symmetry group is the kink moduli space, a structure parallel to the moduli spaces of gauge theoretical topological defects as vortices, [26], or magnetic monopoles, [27].

Identification of the kink variety is achieved through the solution of rst-order, rather than second-order, eld equations. In (1+1)-dimensional scalar eld theories, rst-order equations are available if, modulo a global sign, a superpotential is found. Note that the search for a superpotential is highly non-trivial if $N = 2$. Bazelia et al., however, proposed a continuously differentiable superpotential in their model, which in turn guarantees the stability of any finite energy solution of the associated rst-order system of equations through the classical Bogomolny-Prasad-Sommerfeld eld argument, [28].

The existence of the superpotential tells us that we can understand the system as the bosonic sector of an $N = 1$ (1+1)-dimensional supersymmetric eld theory, in which the kinks play a significant role as BPS states. We shall analyze the supersymmetric extension of this model in a future work, but we observe that the dimension of the kink moduli space in this system is such that the index introduced in [29] is zero, showing that the soliton supermultiplets are long or reducible.

All the foregoing statements are valid for any value of the single classically relevant coupling constant in the model. In this paper we shall show another new result: for certain values of the coupling constant there exists a second superpotential. Accordingly, a second system of rst-order equations is available that also admits kink solutions, although the old and new solitons belong to different topological sectors of the configuration space. For the critical values where the second superpotential is found, there are two non-equivalent supersymmetric extensions of the same bosonic sector.

For most of the critical values the second superpotential fails to be continuously differentiable at a finite number of points in the $R^2$ internal space. In these cases, the second Bogomolny bound
is not a topological quantity; it also depends on the values of the superpotential at the points where it is not differentiable. Kink orbits that cross those points are unstable and are solutions of the first-order equations only in one interval, not on the whole spatial line. Nevertheless, these kinks are solutions of the second-order equations.

A final comment: in concordance with the lifting of the kink translational degeneracy, we expect that the kink internal degeneracy will be removed in second-order in the loop expansion of the energy in the quantum theory.

The paper is organized as follows. In sections x2 and x3 we introduce the BNRT model discussed in [23] and identify a one-parametric family of kinks, which includes the TK1 and TK2 kinks, as BPS solutions. In sections x4 and x5 we investigate the existence of a second decom position ala Bogomol'nyi. We end that this is possible for certain values of the coupling constant, for which we discover a second kink family.

2 The BNRT model

In the model introduced in [23] by Bazeia, Nascentinho, Ribeiro and Toledo, henceforth referred to as the BNR T model, the scalar eld is built from two components \((y) = (_{1}(y);_{2}(y))\) and the dynamics is governed by the action

\[
S[\ ] = \sum_{a=1}^{Z} \int \frac{d^2y}{\theta a} ^{2} \left( \frac{1}{2} a^2 \right)^2 + \frac{1}{2} \left( \frac{1}{2} a^2 \right)^2 + \frac{1}{8} \left( \frac{1}{2} a^2 \right)^2 + \frac{1}{2} \left( \frac{1}{2} a^2 \right)^2 + \frac{1}{2} \frac{1}{2} \frac{1}{2} \right) U(1;2) \tag{1}
\]

Here, \(a\) and \(b\) are coupling constants with dimensions of inverse length and \(a^2\) is a non-dimensional parameter. We use a natural system of units, \(\sim = c = 1\). The energy functional is

\[
E[\ ] = \int \frac{d^2y}{\theta} a \left( \frac{1}{2} \frac{1}{2} \left( \frac{1}{2} a^2 \right)^2 + \frac{1}{2} \left( \frac{1}{2} a^2 \right)^2 + \frac{1}{2} \frac{1}{2} \right) U(1;2) \tag{2}
\]

where \((y) = (_{1}(y);_{2}(y))\). C = \(\mathfrak{M} \mathfrak{R} \mathfrak{P}(R;R^{2}) = E(\mathfrak{y}) < 1\). Introducing non-dimensional elds, variables and parameters, \(a = 2a, b = 2b, y = \frac{1}{a} x, x = \frac{1}{a} x, y = \frac{1}{a} x, \) and \(a = 2, b = 2\), we obtain expressions that are simpler to handle. \(E_{\{1;2\}} = 2a^3 E_{\{1;2\}}\) and the non-dimensional energy functional, which depends on the single classically relevant coupling constant \(a\), is:

\[
E[\ ] = \int \frac{dx}{\theta} \left( \frac{1}{2} \frac{1}{2} \left( \frac{1}{2} a^2 \right)^2 + \frac{1}{2} \left( \frac{1}{2} a^2 \right)^2 + \frac{1}{2} \frac{1}{2} \right) U(1;2) \tag{3}
\]

The Euler-Lagrange equations read:

\[
\frac{d^2_{1}}{dx^2} = 16 \frac{1}{2} \frac{1}{2} + 2 \frac{1}{2} (1 + ) \frac{1}{2} 1 \quad \frac{d^2_{2}}{dx^2} = 8 \frac{1}{2} \frac{1}{2} + 2 \frac{1}{2} \frac{1}{2} 1 \tag{4}
\]

Besides the spatial parity and translational symmetries, there is a global or internal symmetry in this model: the re ection discrete group \(G = Z_{2} Z_{2}\) generated by the transformations \(1 : 1;2\) ! (1;2) and \(2 : 1;2\) ! (1;2) is also a symmetry subgroup of the system.
We shall focus our attention on the $\theta > 0$ regime, where the vacuum manifold is:

$$
M = A_1 = \left(\frac{1}{2}; 0\right); A_2 = \left(\frac{1}{2}; 0\right); B_1 = \left(0; \frac{1}{2}\right); B_2 = \left(0; -\frac{1}{2}\right)
$$

The action of $G$ on $M$ is summarized as follows: $\text{1.}(A_1) = A_2, \text{2.}(B_1) = B_2$. Therefore, $M$ can be seen as the union of two disjoint vacuum orbits: $M = A \cup B$, $A = fA_1; A_2g$, $B = fB_1; B_2g$. The vacuum moduli space $M = \frac{N}{2}$ is a set of two elements, $M = A \cup B$, where $A = \frac{A}{\mathbb{Z}_2}$, and $B = \frac{B}{\mathbb{Z}_2}$. The $G = \mathbb{Z}_2 \times \mathbb{Z}_2$ symmetry of the action (4) is spontaneously broken to the $\mathbb{Z}_2$ subgroup on the elements in the $A$ orbit and to the $\mathbb{Z}_2$ subgroup on the vacua of the $B$ orbit.

Because of the degeneracy and the discreteness of the vacuum manifold $M$, the configuration space is the union of sixteen topologically disconnected sectors. Keeping in mind the symmetries of the model, we identify the non-trivial topological sectors as the $AA$ topological sector (formed by configurations of $C$ that join the $A_1$ and $A_2$ vacua); the $BB$ topological sector (configurations that connect the $B_1$ and $B_2$ vacua), and the $AB$ sector (formed by configurations joining one vacuum in the $A$ orbit with another vacuum in the $B$ orbit).

We use the trial orbit method [1] to show the previously known kink solutions to the equations (6).

1. The $\text{TK}^{1AA}$ kink

First, we try the curve

$$
\text{TK}^{1AA} = \frac{2}{1} = 0; \frac{1}{2}; 1; \frac{1}{2}
$$

This condition is compatible with equations (6) and we find

$$
\text{TK}^{1AA}_1(x) = \frac{1}{2} \tanh \frac{\theta}{2}(x + a); \quad \text{TK}^{1AA}_2(x) = 0
$$

as the one-component topological kinks in the $AA$.

2. The $\text{TK}^{2AA}$ kink:

Second, we try the elliptic orbit

$$
\text{TK}^{2AA} = \frac{2}{1} + \frac{1}{2(1 - \frac{1}{4})} \frac{2}{2} = \frac{1}{4}; \quad \frac{1}{2}; 1; \frac{1}{2}
$$

in (6) and nd in the $AA$ topological sector the two-component topological kinks:

$$
\text{TK}^{2AA}_1(x) = \frac{1}{2} \tanh \frac{\theta}{2}(x + a); \quad \text{TK}^{2AA}_2(x) = \frac{q}{\frac{1}{2}} \sech \frac{\theta}{2}(x + a);
$$

henceforth referred to as $\text{TK}^{2AA}$ kinks.

Note that the orbit (6) gives kink curves only in the $0; 1$ range because if $1$ it becomes a hyperbole that does not connect the vacua. Moreover, (8) describes four different kinks according to the choices of the signs and one can obtain one from another by using the spatial parity and internal reflection symmetries.
The existence of one-component topological kinks—unnoticed in the literature about the model—in the BB topological sectors is obvious.

3. The $TK^{BB}_1$ kink:

Third, we try the orbit

$$TK^{BB}_1 = 1 = 0; \quad \frac{1}{2}\phi_1 + \frac{1}{2}\phi_2$$

in the second-order field equations (9). We immediately nd that the finite energy solutions

$$TK^{BB}_1(x) = 0 \quad TK^{BB}_2(x) = \frac{1}{2}\tanh 2p - (x + a)$$

are the kinks that connect the $B_1$ and $B_2$ vacua.

3. The moduli space of kinks in the AA topological sector

In [16-25] the authors propose a superpotential for the model:

$$U(\phi_1; \phi_2) = \frac{1}{2}\frac{\partial W}{\partial \phi_1}^2 + \frac{1}{2}\frac{\partial W}{\partial \phi_2}^2; \quad W(\phi) = 4p - \frac{1}{3}\frac{1}{4}\frac{1}{2} + \frac{1}{2}\frac{1}{2}$$

Figure 1: The $U(\phi)$ potential (left) and the superpotential $W(\phi)$ (right)

The classical BPS states satisfy the system of rst-order equations

$$\frac{d}{dx}\frac{\partial W}{\partial \phi_1} = 4p - \frac{1}{3}\frac{1}{4}\frac{1}{2}; \quad \frac{d}{dx}\frac{\partial W}{\partial \phi_2} = 4p - \frac{1}{3}\frac{1}{4}\frac{1}{2}$$

which are easier to solve than (9). The superpotential $W(\phi)$ is a smooth function of the fields $\phi_1$ and $\phi_2$ at each point in $R^2$. Therefore, according to the Bogomol'nyi-Prasad-Sommerfield

$$E[\lambda] = \sum_{a=1}^{Z} \frac{\phi_1^2}{2}\frac{\partial W}{\partial \phi_1}^2 + \sum_{a=1}^{Z} \phi_2^2\frac{\partial W}{\partial \phi_2}$$

5
we have that
\[ E[ \gamma] = T[ \gamma] = \int (1(1); 2(1)) \ W (1(1); 2(1))) d\gamma \]
for all solutions of (8) and the kink energy only depends on the topological sector of the solution.

The kink solutions of (8) are the ow -lines of grad W that start and end at elements of M. It happens that \( A_1 \) and \( A_2 \) are respectively maxima and minima of \( W \) and that there are ow -lines of grad \( W \) starting at \( A_1 \) and ending at \( A_2 \) (or vice-versa). \( B_1 \) and \( B_2 \), however, are saddle points of \( W \), see Figure 1. Therefore, there are no ow -lines of grad \( W \) between \( B_1 \) and \( B_2 \) (or vice-versa). Nevertheless, ow -lines of grad \( W \) between one point in the A orbit and another point in the B orbit (or vice-versa) are possible. The ow -lines of grad \( W \) thus provide kinks in the AA and the AB sectors with energies \( E_{TK}^{AA} = \frac{4}{3}a^3 \), \( E_{TK}^{AB} = \frac{2}{3}a^3 \).

To obtain the most general solution to the first-order system (8), we first integrate the first-order ODE
\[ \frac{d_1}{d_2} = \frac{4}{4}(\frac{1}{2} + \frac{\gamma_1}{\gamma_2}) \quad (10) \]
which admits the integrating factor \( j = \gamma_2^{-\frac{1}{2}} \), if \( \gamma_1 \leq 1 \) and \( \gamma_2 \geq 0 \), thereby allowing us to find all the ow -lines as the family of curves
\[ \frac{\gamma_1}{\gamma_2} + \frac{\gamma_2}{\gamma_1} = \frac{1}{4} + \frac{c}{2}j_2 j_1 \quad (11) \]
parametrized by the real integration constant \( c \). There is a critical value
\[ c^* = \frac{1}{41} (2 )^{-1} \]
and the behaviour of a particular curve in the (11) family is described in the following items:

For \( c \in (1, c^*) \), formula (11) describes closed curves in the internal space \( R^2 \) that connect the vacua \( A_1 \) and \( A_2 \), see Figure 2. Thus, they provide a kink family in the topological sector AA. Henceforth, we refer to these kinks as \( TK^{AA} (c) \). A critical value of \( c \) determines four members in the kink variety related amongst one another by spatial parity and internal reflections. The kink moduli space is defined as the quotient of the kink variety by the action of the symmetry group:
\[ M_K = \frac{V_K}{\mathbb{P} G} = (1, c^*) \]
the real open half-line parametrized by \( c \). One sees that
\[ TK^{AA} \quad TK^{AA} (0) \quad TK \lim_{c \to 1} TK^{AA} (c) \]
i.e. the \( TK^{AA} \) kink is the \( c = 0 \) member of the family (if \( c < 1 \)) and the \( TK^{AA} \) kink is not strictly included although it does appear at the boundary of \( M_K \).

In the range \( c \in (c^*, 1) \), equation (11) describes open curves and no vacua are connected. These grad \( W \) ow -lines are infinite energy solutions that do not belong to the configuration space \( C \), see Figure 2.
At the other point of the boundary of $M_K$, $c = c^5$, we find the $TK^{2\AA}$ kinks, which are the separatrices between bounded and unbounded motion and the envelop of all kink orbits in the AA topological sector, see Figure 2.

We briefly discuss the $= 1$ case. The $= 0$ case is not interesting because the $2$ dependence disappears in the potential: it is a \texttt{direct sum} of an $N = 1$ model and an $N = 1$ free model. Integration of (10) when $= 1$ gives

$$
\frac{c}{2} + \frac{\log j}{j} = \frac{1}{4}
$$

(12)

where the kink trajectories now appear in the $c^2 (1; c^5)$ range, with $c^5 = 1 + \ln 2$. The description of the kink orbits is analogous to the description for $61$ above.

![Figure 2: Flow-lines given by (11): for $c^2 (1; c^5)$ (left), $c = c^5$ (middle), and $c^2 (c^5; 1)$ (right).](image)

A second step remains: the explicit dependence of the kinks with respect to the space coordinate can be obtained if we plug (13) into the second equation in (9),

$$
\frac{\partial}{\partial x} = -\frac{2}{4} \int dx:
$$

(13)

The kink solutions are

$$
K \frac{1}{1}(x; c) = \frac{1}{4} + \frac{c}{2} h \frac{1}{2} (4 \frac{P}{2} x) \frac{f}{2(1)} h \frac{1}{2} (4 \frac{P}{2} x) \frac{f}{2(1)}
$$

In general, we cannot obtain the explicit dependence on $x$ for the kink solutions because either we cannot integrate (13) or we cannot identify the inverse of $h(\cdot)$. For certain values of the coupling constant, however, we can finish the task. We next show the family of $TK^{2\AA}$ kinks for $= 2$ and

$$
= 2:
$$

The vacuum points are the vertices of a square: $M_2 = fA_1 = (\frac{1}{2}; 0); A_2 = (\frac{1}{2}; 0); B_1 = (0; \frac{1}{2}); B_2 = (0; \frac{1}{2})$. The quadratures (13) can be solved explicitly and $h \frac{1}{2} \frac{1}{2}$ is a known analytical function. Thus,

$$
TK^{2\AA} \frac{1}{2}(x) = \frac{1}{2} \frac{\sinh 4 \frac{P}{2} x + a}{2 \cosh 4 \frac{P}{2} x + b}
$$

$$
TK^{2\AA} \frac{1}{2}(x) = \frac{1}{2} \frac{\sinh 4 \frac{P}{2} x + a + b}{2 \cosh 4 \frac{P}{2} x + b}
$$
are the kink-form factors. The integration constant \( b \) is related to \( c \) as \( b = \frac{c}{c^4} \), and for \( b \in (1; 1) \) we find kinks in the AA topological sector.

If \( c = c^2 = 4 \), \( b = 1 \) we find the kinks in the AB sector

\[
T_{K}^{2A}(x) = \frac{1}{4} \left(1 + \tanh 2 \frac{P}{2}(x + a)\right) \quad T_{K}^{2B}(x) = \frac{1}{4} \left(1 + \tanh 2 \frac{P}{2}(x + a)\right)
\]

and, replacing \( x \) by \( x \), its antikinks. The separatrices are placed on the edges of the above mentioned square \( 2 = \frac{1}{2} \). The kink trajectories in the AA topological sector form a dense family of curves enveloped by the kink orbits in the AB sector. See Figure 3.

![Kink trajectories](image)

Figure 3: Kink trajectories (left), a kink in the AA sector (middle) and a kink in the AB sector (right) in the case \( b = 2 \).

A rotation of \( 45^\circ \) in \( R^2 \), \( 1 = \frac{1}{2} (1 + 2) \) and \( 2 = \frac{1}{2} (1 - 2) \), shows that for this value of the system is non-coupled: \( U = 2^0 (1; 2) = \frac{1}{32} (\frac{2}{1} \frac{1}{3}) + \frac{1}{2} (\frac{2}{1} \frac{1}{8}) \).

\[
= \frac{1}{2}:
\]

The vacuum manifold is: \( M = \frac{1}{2} = fA_1 = (\frac{1}{2}; 0) ; A_2 = (\frac{1}{2}; 0) ; B_1 = (0; 1) ; B_2 = (0; -1) \). By the same procedure as above, we obtain

\[
T_{K}^{2A}(x) = \frac{1}{4} \sinh 2 \frac{P}{2}(x + a) + b \quad T_{K}^{2B}(x) = \frac{1}{4} \frac{1}{1 + b \cosh 2 \frac{P}{2}(x + a)}
\]

where we have introduced \( b = \frac{1}{4} \). In the \( b \in (0; 1) \) range, the above solutions are kinks that connect the \( A_1 \) and \( A_2 \) vacua (see Figure 4). If \( c = \frac{1}{2} \), \( c^2 \) becomes \( 2^0 + \frac{1}{2}^2 = \frac{1}{4} + \frac{1}{2}^2 \), which can be written as \( (1 + 2^0 \frac{1}{2})(1^2 1 \frac{1}{2}) = 0 \) for \( c = c^s = \frac{1}{4} \). There are kinks on parabolic trajectories joining points in the A and B vacuum orbits

\[
T_{K}^{2A}(x) = \frac{1}{4} 1 \tanh 2 \frac{P}{2}(x + a) \quad T_{K}^{2B}(x) = \frac{1}{2} \frac{1}{1 + \tanh 2 \frac{P}{2}(x + a)}
\]

and, replacing \( x + a \) by \( x - a \), we obtain their antikinks.

4 The second superpotential: \( = 2 \)

For \( = 2 \), \( U = (4^0 1^2 + 4^2 2) )^2 + 64^2 \frac{1}{2} \frac{1}{2} \) does not change if we swap the \( e \) components. There is a second superpotential in the model for \( = 2 \): \( W_0^0 (1; 2) = W_0 (2; 1) \). A second
Figure 4: Kink curves (left), a kink in the AA sector (middle) and a kink in the AB sector (right).

arrangement à la Bogomol'nyi using $W^0(1;2)$ provides another system of first-order differential equations:

\[
\frac{d_1}{dx} = \frac{\partial W^0}{\partial \theta_1} = 8 \frac{p}{2 \theta_1^2} \quad \frac{d_2}{dx} = \frac{\partial W^0}{\partial \theta_2} = \frac{p}{2(\theta_1^2 + \theta_2^2 + 1)}
\]

The owlines of grad $W^0$ connect $B_1$ and $B_2$, which are respectively the maximum and minimum of $W^0$, whereas $A_1$ and $A_2$ are $W^0$ saddle points. We thus obtain a new family of topological kinks, now in the BB sector, with the roles of $1$ and $2$ interchanged: if $b_2(1;1)$,

\[
\begin{align*}
\Phi_{1}^{TK_{2B}^B}(x) & = \frac{1}{2} \frac{p}{\cosh 4 \theta_1^2} \left( \frac{1}{2} + \frac{\theta_1^2}{2} \right) + b \\
\Phi_{2}^{TK_{2B}^B}(x) & = \frac{1}{2} \frac{\sinh 4 \theta_1^2}{\cosh 4 \theta_1^2} \left( \frac{1}{2} + \frac{\theta_1^2}{2} \right) + b 
\end{align*}
\]

are the two-component topological kinks in the BB sector. If $c!1(1;1)$, we nd the $TK_{1B}^B$ kink and if $c=4(1;1)$ the separatrix kinks in the AB sector are reached at the boundary of the component of the moduli space of kinks that belong to the BB sector. The kink energy sum rules are: $E_{TK_{2B}^B} = E_{TK_{1B}^B} = 2E_{TK_{2B}^A} = \frac{1}{2}a^3$.

5 The moduli space of non-BPS kinks in the BB topological sector: $= \frac{1}{2}$

If $\gamma = \frac{1}{2}$, there is also a second superpotential,

\[
W^0(1;2) = \frac{p^2 q}{3} \left( \frac{1}{2} + \frac{\theta_1^2}{2} \right) \left( \frac{2}{1} + \frac{2}{2} \right) \left( \frac{2}{1} + \frac{2}{2} \right) \left( \frac{3}{1} + \frac{2}{2} \right) \right)
\]

that also solves the rst equation in (3). The second system of rst-order equations

\[
\begin{align*}
\frac{d_1}{dx} & = \frac{\partial W^0}{\partial \theta_1} = \frac{p}{2 \theta_1^2} \frac{2(\theta_1^2 + \theta_2^2 + 1)}{\theta_1^2 + \theta_2^2 + 1} \\
\frac{d_2}{dx} & = \frac{\partial W^0}{\partial \theta_2} = \frac{p}{2 \theta_2^2} \frac{2(\theta_1^2 + \theta_2^2 + 1)}{\theta_1^2 + \theta_2^2 + 1}
\end{align*}
\]

rules the os generated by grad $W^0$ in the system. $W^0$ is not differentiable at the origin and the os of grad $W^0$

\[
\begin{align*}
\frac{d_2}{d_1} & = \frac{2(\theta_1^2 + \theta_2^2 + 1)}{1(\theta_1^2 + \theta_2^2 + 1)}
\end{align*}
\]
are undefined at $O(0; 0) \in \mathbb{R}^2$. Note that $B_1$ and $B_2$ are both minima of $W^0$, whereas $A_1$ and $A_2$ are maxima of $W^0$. The origin is the maximum of $W^0$, and thus the ow-lines of grad $W^0$ run from $O$ to either $B_1$ or $B_2$. To obtain a kink orbit, we must glue at $O$ an ow-line of grad $W^0$ with a + ow-line of grad $W^0$ smoothly. Because the ows are undefined at $O$, we expect that an infinite number of lines will meet at the origin.

The Bogomolny splitting must take this into account and the energy of the kink solutions of (16)

$$E[\ ] = \frac{Z_1}{a} \frac{1}{2} \frac{d}{dx} + \frac{d}{dx} \frac{\partial W^0}{\partial \phi} + \frac{Z_a}{2} \frac{d}{dx} \frac{\partial W^0}{\partial \phi} + T(+) + T(-)$$

$$T = T(+) + T(-) = \int W^0(B_1) \ W^0(O) + \int W^0(B_2) \ W^0(O)$$

$E[TK^{2B}] = T(+) + T(-)$ is not topological; it depends on the value of the superpotential at the origin, a sign of instability [10,11]. The kink energy sum rules are: $E_{TK^{2B}} = 2E_{TK^{2A}} = 4E_{TK^{2B}} = \frac{8}{3}a^3$ and the $TK^{2B}$ kinks decay to two $TK^{2A}$ plus one $TK^{2A}$ kinks.

Using parabolic variables, we have shown that the integration of (16) reduces to quadratures in Reference [14]. The translation of our results to Cartesian coordinates is as follows:

The kink orbits that solve (17) satisfy the equation

$$16e^{4e_{zc}} \left( \frac{e_{zc}}{2} + \frac{e_{zc}}{2} \right) + \left( 1 - e^{4e_{zc}} \right)^2 \left( 2 + \frac{e_{zc}}{2} + 1 \right) = 0 \quad (18)$$

and are plotted in Figure 5. Here $c$ is a real integration constant.

![Figure 5: TK $2^B$ (c) Kink family (left) and the superpotential $W^0$ (right)](image)

Analytically, the variety of $TK^{2B}$ (c) kinks is given by:

$$TK^{2B}_1(x) = \frac{\sinh 2y}{\cosh^2 2x + \cosh 2y + 2 \sinh 2y \cosh 2y + 1}$$

$$TK^{2B}_2(x) = \frac{\sinh 2y}{\cosh^2 2x + \cosh 2y + 2 \sinh 2y \cosh 2y + 1}$$

Besides the soliton center $x = a$, the kink family is parametrized by $c$. 

10
Because the spatial translations $T_a : x \rightarrow x + a$ leads from one solution to another and
\[
1 ( T^{K^{2B^b}}_1 (x;c); T^{K^{2B^b}}_2 (x;c)) = ( T^{K^{2B^b}}_1 (x; c); T^{K^{2B^b}}_2 (x; c))
\]
the moduli space of $K^{2B^b}$ kinks—the quotient of the kink variety by the action of $T_a$ and
$T^*$ is the open half-line: $c \in (0;1)$. If, moreover, we take quotient by $P : x \rightarrow x + a$, the
anti-kinks are also included in the moduli space.

The asymptotic behaviour
\[
\lim_{x \rightarrow 1} T^{K^{2B^b}}_1 (x;c) = 0 ; \quad \lim_{x \rightarrow 1} T^{K^{2B^b}}_2 (x;c) = 1
\]
two in with the boundary behaviour, guaranteeing finite energy to the $K^{2B^b}$ (c) kinks. They are
not stable because all of them cross the origin:
\[
T^{K^{2B^b}}_1 (a;c) = 0 ; \quad T^{K^{2B^b}}_2 (a;c) = 0
\]
Thus, only if $x \in (1; a)$ (13-20) are solutions of the first-order equations (16) with the + sign,
whereas they solve (14) with the - sign in the $x \in (a;1)$ range, or vice-versa. It can easily be
proved, however, that these solutions satisfy the second-order differential equations (16).

Things are different at the boundary of the moduli space, the union of the $c = 0$ and $c = 1$
points. Looking at the formula (13) we end the $K^{1B^b}$ kink as the $c = 0$ limit of the kink variety,
whereas the $K^{1A^a}$ kink and two $K^{2B^b}$ kinks—that live on different parabolic branches—are met
at $c = 1$.
